Editorial : Super Spell

Here, inputs of the problem are n & m.
m - how many spell collections that have to be added.
n - how many spells in each collection. So every first line of collection will be n.

Here you have to get the output with the Lexicographic order. For each line of a spell collection, get the letter with minimum ASCII value from each string and construct a new string. Then sort that new string according to the alphabetical order. That will be the output.

Example: If you type m as 3 you can type 3 spell collection. In the first spell collection by input the n as 2 (how many spells) and you can print 2 strings like "***krtyb***" & "***aghf***". From these strings get the minimum ASCII value letter "***b***" & "***a***". Then arrange them with the alphabetical order that is "***ab***". That will be the output for that collection. Like that you can input 3(m) collections and get the Super Spell.
